## I. INTRODUCTION

## A. Background

The streams of northeastern Illinois flow through a tremendously urbanized area. The Chicago metropolitan area includes six counties: Cook, Du Page, Kane, Lake, McHenry and Will. Also present are such large cities as Aurora and Elgin. The fishes inhabitating the streams which flow through this area are a reflection of the primitive fish population of the area's streams and the impact which urbanization has had upon the water quality of these streams.

The need for water quality investigations based upon extensive fish surveys has been recognized. Living organisms are useful indicators of pollution since they concentrate the pollutants in the food chain (which eventually includes $\operatorname{man})$. Also, because they live within the aquatic environment, they are likely to reflect the range of water quality parameters which they have physically endured.

As a group, fishes are tolerant and adaptable organisms that can survive considerable habitat abuse, but the ecological tolerances of the many different species vary tremendously. The mere knowledge that fish exist in a stream indicates nothing about water quality, but knowledge of the assemblage
of species and their numerical relationships provides the ichthyologist with an excellent biological picture of the water course and its well being.

Smith ${ }^{1}$ has already classified the major stream systems in the six-county area. The Des Plaines River system (including the Chicago Channel system) is listed as poor (63 species present) indicating considerable modification of the stream from its original condition. The Fox River system is listed as good to excellent (102 species present).

Recently Bertrand, ${ }^{2}$ Langbein and Wight, ${ }^{3}$ Dennison, ${ }^{4}$ and Sparks and Starrett ${ }^{5}$ have reported results of electrofishing surveys of the Fox River (1975), Des Plaines River (1974), Chicago Channel System (1974 and 1975) and the Illinois River (1959 - 1974), respectively.
B. Objective

An electrofishing survey of the major streams within the Federal "208" Area Wide Waste Treatment Management Plan's area of
interest was carried out during 1976 as an adjunct to a largescale assessment of the water quality of northeastern Illinois streams. C. Scope

The major drainage systems of concern in this program included the Fox River System - Kane, Kendall, Lake and Mc Henry Counties, and the Des Plaines River System - Cook, Du Page, Lake and Will Counties, including the Chicago Channel System - Cook, Lake and Will Counties. Fish were collected from 60 major sampling areas (́..f., Figure l) throughout these two major systems, including as many of the major and minor tributaries as possible.

Major streams and their tributaries within these systems wherein fish sampling was carried out included the following: DES PLAINES RIVER SYSTEM*

```
Des Plaines River
Mill Creek
Bull Creek
Indian Creek
Mc Donald Creek
Feehanville Ditch
Weller's Ditch
Willow Creek
Crystal Creek
Silver Creek
Flag Creek
Sawmill Creek
Black Partridge Creek
Sugar Run Creek
Salt Creek
    Spring Brook
    Ginger Creek
    Addison Creek
Hickory Creek
    Marley Creek
    Spring Creek
```

Tower Lake Drain
Crystal Creek
Jelkes Creek
Tyler Creek
Poblar Creek
Norton Creek
Mill Creek
Indian Creek
Waubansee Creek

Blackberry Creek
Robroy Creek
Big Rock Creek
Little Rock Creek
*Streams are listed in their order of entrance into the major river system, north to south.

## II. SITE SELECTION

## A. Criteria for Selecting Sites

Sixty major sampling areas were to be chosen for collection of fish samples for the 208 program. Criteria set for site selection of these major sampling areas were as follows:

1. In order to determine the distribution of fishes within a a stream system, it is desirable to sample as many areas as possible throughout the reaches of the stream. Therefore, collection efforts will be concentrated within those streams throughout which the greatest number of sampling stations may be distributed in Northeastern I lilinois.
2. Whenever possible, the major sampling areas should be set in sites close to the l0-day chemical sampling stations, for later correlation with these data.
3. The major sampling areas should include subsample sites which are useful for obtaining a correct picture of the water quality of the area, and which are accessible with the gear available.
4. Whenever possible, potential "problem" sites (in terms of adverse effects upon water quality) should be sampled within the major areas.

## B. Description of Site

In order to conduct a fish survey of the streams under study, each site was judged to include different stream habitats within
the major stream and any tributaries near the area in question which may yield information as to possible influences upon the water quality of the major stream.

An example of how a site was investigated is depicted in Figure 2, showing site \#7, Algonquin, on the Fox River. This site included a boat electrofishing sample in the pool upstream of the dam (labeled \#7), and also samples obtained by use of a seine and backpack electrofishing unit within the tailrace of the dam (\#86) and 200 meters downstream of the dam (\#85). Since the tributary, Crystal Creek, entered the Fox River from the west, directly below the Algonquin dam, the mouth of this creek, as well as an area of creek 100 meters upstream from the mouth, was sampled by use of the seine and backpack electrofisher.

A list of each sample site, including a list and description of each subsample area within the site, is given in Table A-l of the Appendix.

Figure 2. Fox River fish sampling area at Algonquin, fish sample site numbers are listed in circles, river miles from the Illinois River in squares
III. PROCEDURE

Depending on the physical conditions of the sampling site (e.g., water depth, bottom type, current velocity) the following gear were used to collect fish specimens:

1. A 230-volt, 180 cycle, 3-phase alternating current (8 - 11 amps), boat-mounted, boom electrofisher followed by a backup boat; fish being stunned and collected with dip nets.
2. A direct current backpack electrofisher yielding 300-400 volts, 0.7 - 0.9 amps; operating from a l2-volt battery; fish being stunned and collected with dip nets. Whenever possible, the backpacker and dipnetters were followed by two men dragging a l5-ft, 3/l6-inch mesh minnow seine.
3. A 30-ft, 3/l6-inch mesh minnow seine 4-ft high with a 4-x4-x4-ft bag was used occasionally when access by the boat shocker was not available and it was deemed necessary to supplement the backpack/seine collection; or when neither the boat shocker nor backpack shocker could be used.
4. The backpack shocker and dip nets alone were used at the tailraces of dams or in other areas where the bottom of the stream contained too much debris for other gear to be useful.
5. An electric seine operating from a ll5-volt generator was also used in a few situations and fish were collected with dip nets and seines as with the backpack-shocker procedure. Since the electric seine proved to be a cumbersome gear, it was not often used.

The following methods were used with the above gear:
The boat shocker: - was used on large streams of sufficient depth and access. Generally a $400-\mathrm{m}$ section of stream was marked off by use of an optical range finder and fish were shocked on both sides of the stream for a total of 800 m of shoreline. In some cases a shorter amount of shoreline was sampled due to physical problems (usually depth); this usually occurred at tributary mouths or in sections of narrow streams where the deep water area was limited.

The backpack shocker/seine: - was used on narrower or shallower streams where a boat shocker was not appropriate. Generally a 40-m section of stream was marked off by use of an optical range finder and fish were shocked either (a), on both sides of the stream for a total of 80 m of shoreline, or if the stream was narrow and the backpack/seine covered all or most of its width then (b), two 40-m sections of stream were measured in line, and a total of 80 m of stream length was sampled. Whenever possible, the $40-\mathrm{m}$ section (or first section of an $80-\mathrm{m}$ section) was begun 100 m upstream of the tributary mouth (if on a tributary) or 150 to 200 m downstream of a dam tailrace if on a major channel.

The $30-\mathrm{ft}, 3 / 16$-inch mesh minnow seine, 4 ft high with a 4 -x4-x4-ft bag: - would be pulled for a certain distance of shoreline in some areas to supplement some collections. In one case it was dragged behind a 14-ft boat equipped with the backpack shocker on the bow. Total length of a haul with the seine alone or with the gear it was used with is listed for each collection site in the Appendix.

The backpack shocker with dip nets alone: - was used for known amounts of time while sampling the tailraces of dams in various streams. It was also used for $40-\mathrm{m}$ lengths of stream which were so filled with debris or rubble that it would have been of little use to have tried to pull a seine behind it. Sampling was done otherwise in the same manner as the backpack/seine, but without a seine.

The electric seine: - was used in narrow streams. Generally a $40-\mathrm{m}$ section of stream was blocked with $3 / 16$-inch minnow seines, and the electric seine, followed by a 3/l6-inch minnow seine and with two dipnetters between the electric seine and minnow seine, was pulled along the stream toward the upstream block seine. This method was repeated 3 or 4 times within the blocked off area in order to collect "all" the fish.

Shocking time was noted for all electrofisher sampling. Distance of stream covered were noted for all methods.

All large fish collected were identified to species, weighed to the nearest gram, and measured for standard length and total length to the nearest millimeter. They were then returned to the stream of capture. Most small fish (less than 80 millimeters total length) were preserved in 10 to $15 \%$ formalin and identified, weighed, and measured in the laboratory.

## IV. WATER QUALITY INDICATORS

## A. Species Diversity

Diversity indices are useful for measuring the quality of an environment for a community of fish species. Their use is based on the generally observed phenomenon that relatively undisturbed environments support communities having large numbers of species with no individual species present in overwhelming abundance. If the species in such a community are ranked on the basis of their numerical abundance, there will be relatively few species with large numbers of individuals and large numbers of species represented by only a few individuals. Many forms of stress tend to reduce diversity by making the environment unsuitable for some species or by giving other species the competitive advantage. ${ }^{6}$

The indices most commonly used to measure "species diversity" in tems of "uncertainty of encounter" are: Brillouin's H and the Shannon ${ }^{9} \cdot \mathrm{H}$ ' (equations (1) and (2) below):
(1) $H=\frac{1}{N}\left(\log N:-\sum_{i}^{S} \log N_{i}:\right)$
where $N_{i}=$ total number of species in the collection;
(2) $\quad H^{\prime}=-\sum_{i}^{S} \frac{N_{i}}{N} \log \frac{N_{i}}{N}$ where $\frac{N_{i}}{N}=p_{i}=$ the relative importance of species ${ }_{i}$ in the sample.

Both of these indices have the three following desirable properties.?

1) for given $s$ the indices are the greatest when $p_{i}=1 / s$ for all species (i.e., the species are distributed with even abundances);
2) given two completely even communities, one with s species and one with $s+1$ species, the latter will have the greater index; and
3) if the community members are subjected to more than one classification (not necessarily independent) the indices can be added. This is useful if one wants to measure generic diversity and species diversity in one number. This can be carried all the way up the hierarchical classification scheme for organisms if one so desires. To be accurate on our use of information theory, the proper index of the two is Brillouin's H. This is the information (entropy) of the collection. Shannon's $H$ ' is considered to be the maximum likelihood estimator of a collection's information when using a random sample rather than the entire collection. There is a correction term for bias and an estimator of the variance defined for $H$ ' if the total number of species in the collection (S) is known (regardless of whether all species occur in the sample).

We recognize that we are not dealing with random samples. We also have to deal with the problem of multiple collection methods. Also, be-tween two localities using the same methods there comes into play numerous factors that limit the comparability of any two collections. Since we feel that most of the error in our collecting would tend to reduce the apparent diversity (usually because our sample size is too small to adequately represent the very patchy nature of a river system) and since $H^{\prime}$
approaches $H$ (population) as sample size increases, we choose to report H'. We do so in terms of numbers of individuals and in terms of gram-weight of the species ( $H^{\prime}{ }_{B}$ ) . We pass along the warning that the smaller the collection the less likely we are to be near the true $H^{\prime}$ of the population and that H's calculated for 40 backpack samples are not directly comparable to boat shocker samples. Where multiple methods are used in the same area they would probably be best used on a per unit effort basis to calculate proportions of species ( $p_{i}$ ) for incorporation into $H^{\prime}$, but this is a matter of interpretation.

Evenness, $J '$, is a measure of the distribution of individuals within an assemblage of species.

$$
J^{\prime}=H^{\prime} / H_{\max }
$$

where $H_{\max }$ is a tabular value of the maximum diversity a given assemblage of species could have, which would be the case when all species in an assemblage had equal numbers of individuals.

## B. Body Condition Factor

In analyzing the success of a population of fish, one is struck by variations in the conditions between individuals of the same species as well as between species.

In waters which contain several species, the variation in condition or plumpness is usually greater between species than between individuals within a species; the bass in a lake may be in good flesh while the bluegills may be thin; at any specific time the variation in condition within a species may not be large. Larger differences may be noted at other
times of the year, or even over longer periods, the latter situation perhaps reflecting long-time changes in food availability, or changes in population density. ${ }^{8}$

General word descriptions of condition are likely to be subjective, and not clear to others interested in this phenomenon. For this reason, several methods have been devised for converting condition to a numerical value which may represent an index which allows for a more objective comparison between populations either on a geographical, time, or species basis. 8

Condition has been expressed in this study by a factor $\mathrm{K}^{10}$ (total body length used in computation) where:

$$
\mathrm{K}=\frac{\mathrm{W} 10^{5}}{\mathrm{~L}^{3}}
$$

where $\mathrm{W}=$ weight in grams
$L=$ length in millimeters
and $10^{5}$ is a factor to bring the value of K near unity.
General long term features, such as environment, food supply and degree of parasitization may affect the fish's condition directly, or where $K$ is correlated with length, via the growth rate and average size. Seasonal changes have frequently been studied with the aid of condition factors, which have been shown to be correlated with gonad cycles, rate of feeding, etc. Short-term cycles of alternating growth in weight and growth in length have also been revealed by the use of condition factors.

## V. RESULTS AND DISCUSSION

Summary statistics for fish length and weight data are listed in Appendix Tables A-2 to A-10. Data as to catch per unit effort (per 30 minutes or 10 minutes electrofishing and per 400 meters or 40 meters of shoreline electrofished) by numbers and by weight and percent (relative abundance) of catch/species by number and by weight, as well as total weight of catch are listed according to each site from which the fish were collected in Appendix Tables All - A24. Data for body condition factor of fish collected are listed in Appendix Tables A25 to A33. The Fox River System was more diverse as to number of species than either the DesPlaines or the Chicago Channel System/Calumet River. A total of 74 species was collected within this system ( 80 varieties , including hybrids and mirror carp), 60 species ( 65 varieties) in the Des Plaines River System, and 31 species ( 35 varieties) in the Chicago Channel System/Calumet River.

Catch statistics for the Fox, DesPlaines and Chicago Channel System are listed in Tables 1 to 4, downstream to upstream. On the average, more species were caught in the Fox River (16) than in the DesPlaines River (10) per sample. Number and weight of catch were greater in the DesPlaines River than in the Fox River (average of 173 individuals at 37 kilograms per DesPlaines sample to 121 individuals at 20 kilograms per Fox River sample) but the species diversity and evenness values were higher in the Fox River (based either on numbers or weight) than in the DesPlaines River, indicating a healthier ecological environment in the Fox River.

* Tributary stations: River mile $303.7=$ Illinois \& Michigan Canal, 40 meters above mouth with Cal - Sag River mile $303.7=\begin{aligned} & \text { Illinois } \\ & \text { Channel }\end{aligned}$
River mile $309.2=$ Stony Creek, 100 meters above mouth with Cal - Sag Channel River mile $319.5=$ Little Calumet River, 2000 meters above junction with Cal - Sag Channel
River mile 325.7 = Crand Calumet River, 2 miles above junction with Calumet River
* Calumet Yacht Club Marina, Lake Michigan, l mile south of Calumet River "mouth" with Lake Michigan, Calumet Harbor

The North Shore Channel/Sanitary and Ship Canal and Calumet River/ Cal-Sag Channel had the lowest numbers of species (5), numbers (77) and weight of catch ( 9 kilograms) per sample than did either the Fox River or the DesPlaines River. Indeed, fish were found to be concentrated mostly in those areas nearest to Lake Michigan, and they do not enter the Chicago Channel System in any appreciable numbers. Diversity and evenness values are of less use here since the low numbers of fish cause them to be insensitive as measures of true water quality for fish life.

Tables 5 to 8 list data for the tributaries of the Fox River, Des Plaines River and the Chicago Channel System. On the average (per sample) tributaries of the Fox River have more species (13), more individuals (148) and greater diversity ( $\mathrm{H}^{\prime}=1.63, \mathrm{H}^{\prime} \mathrm{B}=1.50$ ) and evenness ( $\mathrm{J}^{\prime}=$ $0.65, \mathrm{~J}^{\prime} \mathrm{B}=0.59$ ) than do those of the DesPlaines River ( $\mathrm{S}=6, \mathrm{~N}=61$, $\mathrm{H}^{\prime}=1.13, \mathrm{H}^{\prime}{ }_{\mathrm{B}}=0.87, \mathrm{~J}^{\prime}=0.57, \mathrm{~J}^{\prime} \mathrm{B}=0.42$ ). Again species diversity and evenness become less useful indices in the tributaries of the Chicago Channel System. These tributaries have an average of only 3 species, 24 individuals and 0.1 kilograms per sample.

The greater average weight per sample in the DesPlaines River tributaries ( 1.6 kilograms) than in the Fox River tributaries is attributed to the greater number of carp and goldfish in the former group.

The author would like to thank the other investigators in the Biology Section of the Research and Development Department of the Metropolitan Sanitary District of Greater Chicago who were involved with the field collections, identifications, and the processing of fish, as well as with the analysis of the data, for this project.

They are: Mr. Carl R. Carlson, Jr., Mr. John L. Dorkin, Jr., Mr. Joseph C. Ferencak, Mr. Michael Sopcak and Ms. Janice L. Wagner。

The cooperation of the members of the staff of each of the following agencies and institutions is greatly appreciated:

The Forest Preserve District of Cook County, Illinois The Forest Preserve District of DuPage County, Illinois The Forest Preserve District of Lake County, Illinois The Illinois Department of Conservation The Illinois Environmental Protection Agency The Illinois Natural History Survey The University of Illinois at Chicago Circle
